Complexity of an extended lattice reduction algorithm

Wilberd van der Kallen

December 1998

1 Summary

We consider the complexity of a Lenstra Lenstra Lovász lattice reduction algorithm ([LLL]) in which the vectors are allowed to be linearly dependent and in which one also asks for the matrix of the transformation from the given generators to the reduced basis. The main problem will be to show that the entries of the transformation matrix remain bounded through the algorithm, with a reasonable bound. Here the difficulty is of course that due to the dependence of the generators the transformation is not determined by the basis. To remedy this we work with two inner products and apply the LLL methods to both.

2 Description of GramLatticeReduce

Let $e_1, \ldots, e_n$ be the standard basis of $\mathbb{R}^n$. The input of GramLatticeReduce is the Gram matrix $\text{gram} = ((e_i, e_j))_{i,j=1}^n$ of a positive semidefinite inner product $\langle , \rangle$ on $\mathbb{R}^n$. We assume $\text{gram}$ has integer entries. We are concerned with the lattice $\mathbb{Z}^n$. The output of GramLatticeReduce is an integer rank and an integer matrix $b$ of determinant one. To explain its properties we need some more notation. The ordinary inner product on $\mathbb{R}^n$ is denoted $\langle , \rangle$. Call $v$ isotropic if $\langle v, v \rangle = 0$. Put $\text{isodim} = n - \text{rank}$ and let $b_i^*$ denote the $i$-th Gram-Schmidt vector in the following sense. We have $b_i^* \in (b_i + \sum_{j=1}^{i-1} \mathbb{R}b_j)$ and if $1 \leq j < i$, $j \leq \text{isodim}$ then $\langle b_i^*, b_j \rangle = 0$, but if $1 \leq j < i$, $j > \text{isodim}$ then $\langle b_i^*, b_j \rangle = 0$. With those notations the output satisfies:
1. The first \( \text{isodim} \) rows \( b_i \) of \( b \) are isotropic.

2. With respect to \( (\ , \ ) \) the first \( \text{isodim} \) rows of \( b \) form an LLL reduced basis of \( \sum_{j=1}^{\text{isodim}} \mathbb{Z}b_i \).

3. With respect to \( (\ , \ ) \) the last \( \text{rank} \) rows of \( b \) form an LLL reduced basis of the lattice they span, and this lattice contains no nonzero isotropic vector.

4. For \( 1 \leq i \leq \text{isodim}, \ i < j \leq n \) we have \( |\langle b_i^*, b_j \rangle| \leq 1/2\langle b_i^*, b_i \rangle \).

**Remark 2.1** Variations are possible, depending on what one is really after. If one is only interested in the isotropic vectors, one may weaken condition 3 to

3’ The last \( \text{rank} \) rows of \( b \) form a basis of the lattice they span, and this lattice contains no nonzero isotropic vector. Furthermore, \( |\langle b_i^*, b_j \rangle| \leq 1/2\langle b_i^*, b_i \rangle \) for \( n - \text{rank} + 1 \leq i \leq n \), \( i < j \leq n \).

Similarly, one may wish to replaces condition 2 with

2’ For \( 1 \leq i \leq \text{isodim}, i < j \leq \text{isodim} \) we have \( |\langle b_i^*, b_j \rangle| \leq 1/2\langle b_i^*, b_i \rangle \).

These changes do not affect our analysis in any essential way. One just has to change the wording, not the formulas. And in the algorithm one has to leave out some swaps.

## 3 Description of \texttt{ExtendedLatticeReduce}

Given generators \( b_1, \ldots, b_n \) of a sublattice of \( \mathbb{Z}^m \), the algorithm \texttt{ExtendedLatticeReduce} basically just calls \texttt{GramLatticeReduce} with as input the Gram matrix \( ((b_i, b_j))_{i,j=1}^n \).

## 4 Sketch of the algorithm

We assume the reader is familiar with [LLL] and also with the implementation of the LLL algorithm in integer arithmetic, as described in [C].

Most of the time we are given

- An integer matrix \( b \) of determinant one,
• Integers $k$, $k_{\max}$, $1 \leq k \leq k_{\max} \leq n$.

• An integer $isodim \geq 0$, so that the first $isodim$ rows $b_i$ of $b$ span the isotropic subspace of $\sum_{j=1}^{k_{\max}} \mathbb{R}b_j$.

(Initialize with $k = k_{\max} = 1$ and $isodim = 0$.)

Let $pr_{iso}$ be the orthogonal projection according to $(\ , \ )$ of $\mathbb{R}^n$ onto $\sum_{j=1}^{isodim} \mathbb{R}b_j$ and put

$$(v, w)_{\text{mix}} = (pr_{iso}v, pr_{iso}w) + \langle v, w \rangle.$$

Let $\mu_{i,j}$ be defined for $i>j$ so that

$$b_i = b^*_i + \sum_{j=1}^{i-1} \mu_{i,j}b^*_j.$$

The first standard assumption is then that, with respect to $(\ , \ )_{\text{mix}}$, the first $k-1$ rows of $b$ form an LLL reduced basis of $\sum_{j=1}^{k-1} \mathbb{Z}b_j$, except that one does not require

$$|b^*_i + \mu_{i,i-1}b^*_i|_{\text{mix}}^2 \geq 3/4|b^*_{i-1}|_{\text{mix}}^2$$

when $i = isodim + 1$. And the second standard assumption is that, as in [C], the first $k_{\max}$ rows of $b$ form a basis of $\sum_{j=1}^{k_{\max}} \mathbb{Z}e_i$.

We run the LLL algorithm with respect to $(\ , \ )_{\text{mix}}$, except that one never swaps $b_{isodim}$ with $b_{isodim+1}$. This roughly amounts to running two LLL algorithms, one for $(\ , \ )$ and one for $(\ , \ )_{\text{mix}}$. That is how one implements it and that is how we would have told it if we had not needed $(\ , \ )_{\text{mix}}$ for the complexity analysis. One runs LLL until $k$ tries to go to $k_{\max} + 1$. If $k_{\max} = n$ we are through. If $k_{\max} < n$ and $\sum_{j=1}^{k_{\max}+1} \mathbb{Z}b_j$ contains no more isotropic vectors than $\sum_{j=1}^{k_{\max}} \mathbb{Z}b_j$, then we simply increase $k_{\max}$ by one.

In the remaining case we have to work until we are back in the standard situation with $k = 2$ and with both $isodim$ and $k_{\max}$ one bigger. This is what $\text{trickledown}$ is for. We postpone its discussion. At the end of $\text{trickledown}$ we also make that $|\mu_{i,j}| \leq 1/2$ for $j < i \leq k_{\max}$. This may not be necessary (and indeed we did not do this in earlier versions) but it can do little harm and definitely simplifies the estimates below.
5 Estimates

We want to give estimates as in [LLL]. Thus let $B \geq 2$ so that the entries of gram are at most $B$. Our main result is that all through the algorithm all entries have bit length $O(n \log(nB))$. We do not care about the constants in this estimate. We leave to the reader the easy task of estimating the number of operations in the algorithm in the manner of [LLL].

5.1 Determinants

Let $\text{gram}_\text{mix}$ be the Gram matrix $((e_i, e_j)_\text{mix})$ with respect to $e_1, \ldots, e_\text{kmax}$. Its entries are at most $B + 1$. With Hadamard this gives

$$|\det(\text{gram}_\text{mix})| \leq (\sqrt{n}(B + 1))^n$$

and the same estimate holds for its subdeterminants. We claim that the determinant of $\text{gram}_\text{mix}$ is an integer, so that we also get this upper bound for the entries of $\text{gram}^{-1}_\text{mix}$. To see the claim, consider as in [P] the inner product $(\ , \)\epsilon$ given by $(v, w)_\epsilon = \epsilon(v, w) + \langle v, w \rangle$. Its Gram matrix has a determinant which is a polynomial $\det_\epsilon$ of $\epsilon$ with integer coefficients. One may also compute $\det_\epsilon$ with respect to a basis which is obtained from $e_1, \ldots, e_\text{kmax}$ through an orthogonal transformation matrix. By diagonalizing the Gram matrix of $\langle \ , \ \rangle$ we see that $\det(\text{gram}_\text{mix})$ is the coefficient of $\epsilon^{\text{isodim}}$ in $\det_\epsilon$. \hfill \Box

Lemma 5.2 For $v \in \mathbb{R}^n$ one has

$$(v, v)_\text{mix} \leq n(B + 1)(v, v)$$

and for $v \in \sum_{j=1}^{\text{kmax}} \mathbb{R}e_j$ one has

$$(v, v) \leq n(\sqrt{n}(B + 1))^n(v, v)_\text{mix}.$$ 

Proof

The supremum of $\{(v, v)_\text{mix} \mid (v, v) = 1\}$ is the largest eigenvalue of the gram matrix of $\langle \ , \ \rangle_\text{mix}$ with respect to $e_1, \ldots, e_n$. The largest eigenvalue is no larger than the trace of this matrix. So it is at most $n(B + 1)$. Similarly the largest eigenvalue of $\text{gram}^{-1}_\text{mix}$ it is at most $n(\sqrt{n}(B + 1))^n$. \hfill \Box
5.3 Vectors

Now put

$$\text{diso}_i = \prod_{j=1}^{i} (b^*_j, b^*_j)$$

for $i \leq \text{isodim}$ and

$$d_i = \prod_{j=1}^{i} \langle b^*_j + \text{isodim}, b^*_j + \text{isodim} \rangle$$

for $i \leq \text{rank}$. As far as $d_i$ is concerned we may compute modulo isotropic vectors, or also with $(\ , \)_{\text{mix}}$. Indeed

$$\langle b^*_j + \text{isodim}, b^*_j + \text{isodim} \rangle = (b^*_j + \text{isodim}, b^*_j + \text{isodim})_{\text{mix}}$$

for $1 \leq j \leq \text{rank}$. Both $\text{diso}_i$ and $d_j$ are integers and they descend when applying LLL.

One may also compute $\det(\text{gram}_{\text{mix}})$ with the $b^*_i$ basis, as the transition matrix has determinant one. From that one sees that it is just $\text{diso}_{\text{isodim}} d_{\text{rank}}$. So we get $\text{diso}_{\text{isodim}} \leq (\sqrt{n}(B + 1))^n$. In fact, for $i \leq \text{isodim}$ one has the same estimate

$$\text{diso}_i \leq (\sqrt{n}(B + 1))^n$$

because $i$ was equal to $\text{isodim}$ earlier in the algorithm and LLL only makes it go down. Similarly $d_{\text{rank}} \leq (\sqrt{n}(B + 1))^n$, but actually we know from [LLL] that

$$d_i \leq B^i.$$

(This is not spoiled by trickledown which also makes $d_i$ descend.)

**Lemma 5.4** Let $1 \leq i \leq \text{kmax}$. Then

$$(\sqrt{n}(B + 1))^{-n} \leq (b^*_i, b^*_i)_{\text{mix}} \leq (\sqrt{n}(B + 1))^n$$

and if $|\mu_{ij}| \leq 1/2$ for $1 \leq j < i$ then

$$(b_i, b_i)_{\text{mix}} \leq n(\sqrt{n}(B + 1))^n$$

□

**Remark 5.5** These estimates are not as sharp as those in [LLL] but that can not be helped: It is no longer true that $(b^*_i, b^*_i) \leq B$. Consider for instance the quadratic form $\langle v, v \rangle = \sum_{i=1}^{n-1} (Nx_i - x_{i+1})^2$ for some large integer $N$. The shortest nonzero isotropic vector in $\mathbb{Z}^n$ is $(1, N, N^2, \ldots, N^n)$. 5
5.6 Preserved estimates

Lemma 5.7 The following estimates hold between applications of trickledown.

1. \( \text{diso}_i \leq (\sqrt{n}(B + 1))^n \) for \( i \leq \text{isodim} \),
2. \( d_i \leq B^i \) for \( i \leq \text{rank} \),
3. \( (b_i, b_i)_{\text{mix}} \leq n(\sqrt{n}(B + 1))^n \) for \( i \neq k \),
4. \( (b_k, b_k)_{\text{mix}} \leq n^2 4^n (\sqrt{n}(B + 1))^{3n} \),
5. \( |\mu_{i,j}| \leq 1/2 \) for \( 1 \leq j \leq i < k \),
6. \( |\mu_{k,j}| \leq 2^{n-k} \sqrt{n}(\sqrt{n}(B + 1))^n \) for \( 1 \leq j < k \),
7. \( |\mu_{i,j}| \leq \sqrt{n}(\sqrt{n}(B + 1))^n \) for \( 1 \leq j < i > k \).

Proof

That these are preserved under LLL follows as in [LLL], so one has to check that they hold right after trickledown. Given our earlier estimates this is straightforward. \( \square \)

6 Description of trickledown

Before we can do estimates concerning trickledown we must describe it. One starts with having \( k = k_{\text{max}} + 1 \leq n \). Consider the lattice generated by \( b_1, \ldots, b_{k_{\text{max}}+1} \) where \( b_{k_{\text{max}}+1} = e_{k_{\text{max}}+1} \). By assumption this lattice contains a nonzero vector \( v \) with \( (v,v)_{\text{mix}} = 0 \). Modulo \( \mathbb{R} v \) the vector \( b_k \) is linearly dependent on the \( b_i \) with \( i < k \). Changing the basis of \( \mathbb{Z} b_{k-1} + \mathbb{Z} b_k \) we can achieve that modulo \( \mathbb{R} v \) the vector \( b_{k-1} \) is linearly dependent on the \( b_i \) with \( i < k - 1 \). Then lower \( k \) by one and repeat until \( k = \text{isodim} + 1 \), where \( \text{isodim} \) is the one from before the present trickledown. At that point \( b_k \) is itself isotropic and we increase \( \text{isodim} \) by one and pass to a new \( (\cdot,\cdot)_{\text{mix}} \). After subtracting suitable multiples of \( b_j \) with \( j < i \) from \( b_i \) for all \( i \) we arrive at the situation where \( |\mu_{i,j}| \leq 1/2 \) and we leave trickledown with \( k = 2 \) (or \( k = \max(\text{isodim},2) \)) and with \( k_{\text{max}} \) increased by one.
7 Estimates during trickledown

We look in more detail. Upon entering trickledown we freeze the old isodim, kmax and the $b_i^*$, even though the $b_i$ will change. We also do not change $(\ldots)$ mix. Let $\mu_{i,0}$ stand for $(e_{kmax+1}, b_i)$ and let $\mu_{i,j}$ stand for $(b_j^*, b_i^*)_{\text{mix}}/[(b_j^*, b_j^*)_{\text{mix}}$ if $j > 0$. Note that initially $|\mu_{i,j}| \leq 1$ for $i \leq kmax$, $0 \leq j \leq kmax$. We will estimate $|\mu_{i,j}|$ as $k$ descends.

Say $k > \text{isodim} + 1$ and modulo $\mathbb{R}v$ the vector $b_k$ is linearly dependent on the $b_i$ with $i < k$. Let us compute with $b_k, b_{k-1}$ modulo $V = \mathbb{R}v + \sum_{i=1}^{k-2} \mathbb{R}b_i$. We have $b_k \equiv b_{k-1} \equiv \mu_{k,k-1}^{*}$. As we are recording the euclidean algorithm of [C] we find an integer matrix

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}$$

one so that

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \begin{pmatrix} 1 \\ \mu_{k,k-1} \end{pmatrix} = \begin{pmatrix} 0 \\ -1/r_k \end{pmatrix}$$

where $r_k$ is the index of $\mathbb{Z}$ in $\mathbb{Z} + \mathbb{Z}u_{k,k-1}$. More specifically, one has

$$\begin{pmatrix} \delta & -\beta \\ -\gamma & \alpha \end{pmatrix} \begin{pmatrix} 0 \\ -1/r_k \end{pmatrix} = \begin{pmatrix} 1 \\ \mu_{k,k-1} \end{pmatrix}$$

so $\beta = r_k$ and $\alpha = -r_k\mu_{k,k-1}$. By [C] we have $|\gamma| \leq |\mu_{k,k-1}r_k|$ and $|\delta| \leq r_k$. (Here we assume for simplicity that $\mu_{k,k-1}$ is not zero.)

Now put $c_{k-1} = \alpha b_{k-1} + \beta b_k$ and $c_k = \gamma b_{k-1} + \delta b_k$. The algorithm will tell us to replace $b_k$ with $c_k$ and $b_{k-1}$ with $c_{k-1}$. We want to estimate the resulting new $\mu_{i,j}$, which we call $\nu_{i,j}$. For $i$ different from $k, k-1$ nothing changes. Further $|\nu_{k-1,j}| = |\alpha \mu_{k-1,j} + \beta \mu_{j,k}| \leq r_k |\mu_{k,k-1} \mu_{k-1,j}| + r_k |\mu_{j,k}|$ and $|\nu_{k,j}| = |\gamma \mu_{k-1,j} + \delta \mu_{j,k}| \leq r_k |\mu_{k,k-1} \mu_{k-1,j}| + r_k |\mu_{j,k}|$, which is the same bound.

Remark 7.1 During trickledown the $d_i$ are repeatedly replaced by divisors. As we are recording the $\mu_{i,j}$ with $j > \text{isodim}$ as fractions with a denominator $d_j - \text{isodim}$, this means that one has to update the numerators too. By remembering the $r_k$ one can postpone all this updating until the end of trickledown, processing the product of the corrections, rather than each correction separately.

Lemma 7.2 As $k$ descends we have

1. $|\mu_{i,j}| \leq 1$ for $k > i > j \geq 0$,
2. $|\mu_{i,j}| \leq \sqrt{B}((\sqrt{n}(B + 1))^{n/2} \prod_{i=k+1}^{kmax+1} (2r_i)$ for $k > j \geq 0$,
3. $|\mu_{i,j}| \leq 2^n n^{n/4} (B + 1)^n$ for $k \leq i > j \geq 0$. 

7
Proof
Initially we have $k = k_{\text{max}} + 1$ and we estimate $|\mu_{k,j}|^2 \leq B(b^*_j, b^*_j)_{\text{mix}} \leq B(\sqrt{n}(B + 1))^n$. Now assume the estimates are true for the present $k$. We get $|\nu_{k-1,j}| \leq r_k |\mu_{k,k-1}\mu_{k-1,j}| + r_k |\mu_{k,j}| \leq 2r_k \max_j |\mu_{k,j}|$ which takes care of $|\nu_{k-1,j}|$. As $\prod_{k=\text{isodim}+2}^{\text{isodim}+1} r_k^2$ is the ratio by which $d_{\text{rank}}$ drops during trickledown, it is at most $B^{\text{rank}}$. So $|\nu_{k,j}| \leq \sqrt{B}(\sqrt{n}(B + 1))^{n/2} 2^n B^{\text{rank}/2}$. □

Remark 7.3 Experiments show it is wise to insert a reduce step to make that $|\mu_{k,j}| \leq 1/2$ for $j \neq 0$.

7.4 Increasing isodim
When $k$ has reached isodim + 1 it is time to increase isodim by one and pass to a new $(,)_\text{mix}$. But first use the estimates of the $\mu_{i,j}$ to estimate $(b_i, b_i)_{\text{mix}}$ and $(\mu_{i,0}\epsilon_{k_{\text{max}}+1}, \mu_{i,0}\epsilon_{k_{\text{max}}+1})_{\text{mix}}$, next $(b_i - \mu_{i,0}\epsilon_{k_{\text{max}}+1}, b_i - \mu_{i,0}\epsilon_{k_{\text{max}}+1})$ by means of Lemma 5.2, and finally $(b_i, b_i)$.

Now change isodim, kmax, $(,)_\text{mix}$. We have to compute the new $\mu_{j,\text{isodim}}$. They can be estimated, as we have an estimate for $(b_j, b_j)$ and for $(b^*_{\text{isodim}}, b^*_{\text{isodim}})^{-1}_{\text{mix}}$.

Finally we reduce to the case $|\mu_{i,j}| \leq 1/2$ for $i > j$. During this reduction the maximum of the $|\mu_{i,j}|$ gets at most $2^n$ as large by the argument in [LLL].

We have seen that all the integers that are encountered have bit length $O(n \log(nB))$.

8 Implementation in Mathematica

(*:Name: NumberTheory'LLLalgorithm‘ *)

(*:Summary: The extended Lenstra Lenstra Lovasz algorithm finds *)
(* a lattice basis consisting of "short" vectors, *)
(* together with a transformation that relates the new *)
(* basis with the original set of generators. Instead of *)
(* giving a generating set directly, one may also give *)
(* its Gram matrix. When the generators are linearly *)
(* dependent, a reduced basis of the lattice of relations *)
(* ("null space lattice") is also obtained. *)

8
We add \texttt{ExtendedLatticeReduce} and \texttt{GramLatticeReduce} to the \texttt{builtin} function \texttt{LatticeReduce}.

\texttt{BeginPackage["LLLalgorithm"]}

\texttt{ExtendedLatticeReduce::usage:=}
"ExtendedLatticeReduce\{v1, v2, \ldots\} gives
\{reduced basis, transformation\}
where the transformation is an integral matrix \texttt{T} of determinant plus or
minus one such that the rows of \texttt{T}\{v1, v2, \ldots\} form a reduced basis,
possibly preceded by zero vectors. These zero vectors occur if the integral vectors \( v_i \) are linearly dependent. In that case the corresponding top part of \( T \) is a reduced basis of the 'null space lattice'.

\[
\text{GramLatticeReduce}::\text{usage}:=
"\text{GramLatticeReduce}[\{\{v_i . v_j\}\}] \text{ gives \{rank of lattice,transformation\} where the transformation is an integral matrix} \ T \text{ of determinant plus or minus one such that the rows of} \ T \cdot \{v_1, v_2, \ldots\} \text{ form a reduced basis, possibly preceded by zero vectors. These zero vectors occur if the vectors} \ v_i \text{ are linearly dependent.}\n\]
The Gram matrix \( \{v_i . v_j\} \) should have rational entries.

\[
\text{RatioLLLCondition}::\text{usage}:="\text{RatioLLLCondition is an option in ExtendedLatticeReduce and in GramLatticeReduce. It tells which ratio to use in the criterion for an LLL reduced basis. The default is 3/4, but for some applications one should take it closer to one.}\n\]
\text{RatioLLLCondition}->\{3/4,19/20,99/100\} \text{ causes three passes, with ratios 3/4, 19/20, 99/100 respectively.}\]

(*:Examples:

9 Implementation in GP/PARI

\hspace{1cm} Extended Lenstra Lenstra Lovasz algorithm.
\hspace{1cm}
\hspace{1cm} NAME extendedlll
\hspace{1cm}
\hspace{1cm} DESCRIPTION
\hspace{1cm}
\hspace{1cm} By default extendedlll computes LLL reduced bases of both the lattice L spanned by the generating set and the lattice R of integer relations between the generators. It is an extended algorithm in that it returns the needed transformation as second entry.
\hspace{1cm}
\hspace{1cm} SYNOPSIS
\hspace{1cm}
\hspace{1cm} extendedlll(m[,isgram[,reducecolumnspaceoff[,reducerelationsoff]]])
\hspace{1cm}
\hspace{1cm} Here isgram, reducecolumnspaceoff, reducerelationsoff are 0 or 1.

\hspace{1cm} PROGRAM
\hspace{1cm}
extendedlll(X,
\hspace{1cm} \hspace{1cm} X is matrix with integer entries
\hspace{1cm} \hspace{1cm}
\hspace{1cm} OPTIONS
\hspace{1cm} \hspace{1cm}
isgram,\n\hspace{1cm} \hspace{1cm} isgram is an option to indicate, by means of value 1, that the matrix X should be understood as Gram matrix. If isgram is 0 or absent, then the columns of the matrix X are understood as generators of the lattice L.
\hspace{1cm} reducecolumnspaceoff,\n\hspace{1cm} \hspace{1cm} option to indicate if nonreduced basis of the lattice L is acceptable.
\% option to indicate if nonreduced basis of the relation lattice $R$ is acceptable.
