†IBM, The Netherlands

Abstract—This paper presents the findings of a case study of a large scale legacy to service-oriented architecture migration process in the payments domain of a Dutch bank. The paper presents the business drivers that initiated the migration, and describes a 4-phase migration process. For each phase, the paper details benefits of using the techniques, best practices that contribute to the success, and possible challenges that are faced during migration. Based on these observations, the findings are discussed as lessons learned, including the implications of using reverse engineering techniques to facilitate the migration process, adopting a pragmatic migration realization approach, emphasizing the organizational and business perspectives, and harvesting knowledge of the system throughout the system’s life cycle.

I. INTRODUCTION

In the current business environment, enterprises are pressured to respond to changes in the market, laws and regulations, and to remain efficient and innovative to reap benefits from on-demand and new business opportunities. In order to manage these changes and remain competitive, flexibility is required within the enterprise, supported by technology [1]. Technology support itself is constantly evolving with the advancement of new computing paradigms and improvements in hardware infrastructures. Enterprise systems should therefore be designed to enable continuous evolution and to remain responsive to new business opportunities, realizing better reuse and maintainability, and to improve business-IT alignment to achieve business goals [1]. One of the obstacles to adapt to such changes is the presence of legacy systems [2]. Despite their well-known disadvantages, such as being inflexible and hard to maintain, legacy systems are still vitally important to enterprises as they support complex core business processes; they cannot simply be removed as they implement and execute critical business logic effectively and accurately. Unsurprisingly, the knowledge contained in these systems is of significant value to an enterprise. On the other hand, proper documentation, skilled manpower, and resources to evolve these legacy systems are scarce. Therefore, momentum is growing to evolve those legacy systems within new technological environments such as Service-Oriented Architecture (SOA) as SOA facilitates the reuse of existing assets [3].

The SOA paradigm is favored by loose-coupling, flexible composition of business services, re-usability, and abstraction from the underlying technology platforms. Hence, migration from legacy systems to SOA enables enterprises to achieve flexibility for collaboration, agility within a constantly changing environment [3] and thus enabling business-IT alignment. With these claimed benefits, there has been an increasing interest in academia to investigate approaches for migrating legacy systems to SOA [4].

This paper presents the findings of a case study of the migration of a large scale legacy system from a Dutch bank to a SOA. For reasons of confidentiality, hereinafter the bank is referred to as “NedBank”. The paper describes a 4-phase migration process that is used in NedBank. For each phase, the paper identifies the benefits of using particular techniques/methods within that phase, best practices that helped to achieve success, and possible challenges that were faced during migration. Based on these observations, the paper presents the lessons learned from the case study. The findings of the paper not only emphasize the benefits of using reverse engineering techniques to facilitate the migration process, but also urges academia to pay attention to business and organizational aspects. The business and organizational aspects include governance of the migration process, early involvement of the existing technical staff, and knowledge harvesting of the system.

The paper is structured as follows: Section II discusses related work; Section III explains the research approach and current technological landscape of the payments domain of NedBank; Section IV presents the migration process and discusses benefits, best practices and challenges faced during the migration; Section V analyzes and presents the findings as lessons learned. In Section VI, the paper concludes with some potential future work.

II. RELATED WORK

De Lucia et al. [5] describe an approach and tools to migrate legacy applications to web applications. Sneed [6], [7] has contributed several wrapping techniques to migrate COBOL applications to SOA. A plethora of research has been reported on migrating legacy applications to SOA. They are reflected in the survey [4]. However, considerably fewer real world case studies of legacy to SOA migration are reported. Nasr et al. [8] describe two large scale industrial case studies of legacy to SOA migration; Colosimo et al. [9] present an empirical study.
of legacy migration in Italian companies; Kokko et al. [10] report on SOA adoption process in nine Finnish organizations.

The use of reverse engineering techniques in software evolution has been extensively researched. Various research roadmaps and surveys (e.g., Bennett et al. [11], Muller et al. [12], Canfora et al. [13]) have been presented. As per the interest of this research, extracting program quality metrics has been reported in [14], [15] and details of use of software visualization in reverse engineering & re-engineering has been reported in a survey by Koschke [16]. Data-intensive legacy system migration has been reported by Henrard et al. [17].

III. RESEARCH BACKGROUND

The current research has adopted an exploratory case study method [18], primarily reporting on how the migration is carried out and seeking new insights about which activities are performed during migration. Data collection in this case study is performed based on the participant observation method [18], wherein two of the researchers were directly involved in the migration project. The data collection included the following: (i) consulting documentation to identify the need for and goals of the migration process; (ii) workshops & informal discussions to discuss the progress of the migration in real time, and (iii) semi-structured interviews to understand various aspects of the migration process. In total six semi-structured interviews were conducted. The interviews were conducted in English and lasted between 60-120 minutes. Prior to the interviews, each expert was introduced to an interview protocol, a document detailing the objectives of the interview with some sample questions, and a glossary of the technical terms to attain a common understanding.

Research Context: NedBank is one of the largest banks in the Netherlands with more than 900 branches worldwide. Triggered by the Single Euro Payment Area (SEPA) initiative of the European Union, NedBank started the migration of its core banking systems under a project that started in 2010 and is expected to end in 2018. The main objective of this project is to renovate and migrate its legacy systems to SOA. The estimated cost of the project is 600M Euro. The project is subdivided into 6 different portfolios: channel support, payments, current accounts, customer reporting, counter, and sales & product agreements. After an initial investigation, this research is scoped to the migration of the payments domain because of the following two reasons: (i) the subsystems within the payments domain are diverse with respective to programming languages, hardware and operating systems in use, and (ii) the payments domain is of prime importance in the day-to-day operation of the banking business.

The payments domain is responsible for the overall management of banking transactions including foreign transactions, and interest & cost calculation per transaction of NedBank customers. The subsystems within the payments domain are considered to have high impact on the business of NedBank and have a high priority within the banking system. The payments domain was one of the first domains to adopt automatization in NedBank. Over the years, the subsystems of the payments domain have been subjected to frequent changes which have resulted in a “spaghetti architecture” [19] posing long-term problems such as increased complexity, inflexible changes and evolution, and increasing maintenance and running costs. Currently, the payments domain consists of five major legacy subsystems as detailed in Table I.

To better understand the basic working principles of and dependencies between these systems, a use case is described in which a customer is created and (s)he withdraws money from an Automated Teller Machine (ATM). Figure 1 depicts a high level sequence diagram, in which every directed edge between two subsystems implies a coupling between the two.

A new contract for opening an account is created in a Siebel-based sales environment in one of the local branches. During the account opening process, Siebel requests several AccountAgreement services in order to get an account number and to create agreements for the customer. The account and agreement creation are processed in real-time. Upon opening an account for a customer, the other four subsystems (BalanceCheck, ReportCustomer, ForeignAccount and CalculateInterest) are updated accordingly. When the customer withdraws money from an ATM, initially the request is validated with the agreements stored in the BalanceCheck subsystem and the withdrawn amount is reserved from the customer’s account. Such individual banking transactions are stored in a flat file and at the end of the day, the flat file is updated with the transactional information from the ForeignAccount subsystem: a subsystem responsible for recording the foreign transactions. Afterwards, the flat file is processed by the CalculateInterest subsystem that is responsible for interest, commission and
cost calculations, and synchronizing the updated records to the other subsystems.

From the information in Table I, it is obvious that the subsystems of the payments domain are combined with heterogeneous IT infrastructures with variations in the COBOL dialects used, and the hardware platforms on which they operate. The subsystems range from internally developed subsystems like \texttt{CalculateInterest} to third party built-in packaged subsystems such as \texttt{ForeignAccount}. The subsystems are efficient in terms of performance, capable of effectively analyzing, processing and synchronizing millions of records. Nevertheless, to achieve such performance, various features within the subsystems are duplicated and/or updated in ad-hoc manner, increasing system complexity. The increase in complexity has now become a bottleneck to the changeability of the subsystems within the payments domain.

Additionally, based on our observations (interview, documentation, workshops and informal discussion), the main business goals of the NedBank upon migrating to a SOA are (i) accelerating time-to-market, (ii) reducing costs in the payments domain, (iii) transparency in ownership & governance of the products, and (iv) preventing knowledge erosion.

IV. THE MIGRATION PROCESS

In this section, we explain the legacy to SOA migration process of the payments domain. Due to the complexity and tight coupling between the subsystems of the payments domain, the activities within the migration process are performed in a phased, controlled manner based on the business priorities. The migration approach consists of the following four phases, being: (i) Forming a migration program management committee, (ii) Developing a logical target-architecture, (iii) Analyzing the gap, and (iv) Realizing the migration.

A. Forming a Migration Program Management Committee

The legacy to SOA migration process needs to be capable of addressing various kinds of issues including business, organizational and technical issues [8]. The migration process involves a long term investment of resources and is aimed at conducting a large-scale migration by performing activities with minimal dependencies and maximal parallelization. Thus, to establish a suitable planning and management, a governing body, the \textit{Program Management Committee}, was created. It includes various stakeholders representing senior management officials, business architects representing the different business units, software architects and technical managers, external consultants and application developers. The committee is divided into the following teams with specific responsibilities: a \textit{Steering Committee} to develop a strategic policy for the migration; a \textit{Core Team} to develop the business-IT alignment strategy; a \textit{Program Management} team to manage the payment portfolio; a \textit{Business Change Management} team to ensure proper alignment of business goals with the IT architecture; and an \textit{Architecture Board} to develop an architectural governance within the payments domain. The role of the \textit{Business Change Management and Architecture Board} is crucial, in particular, in developing and executing the migration process, aligning the business goals with the architectural requirements, and coordinating architectural priorities inline with the business goals.

B. Developing a Logical Target-Architecture

Initially, a logical target-architecture conforming to the business goals was developed. A logical target-architecture forms the organizing logic for business processes and IT infrastructure, in which the business components are contained. Developing a logical target-architecture that conforms to the business goal was not an easy task. To start with, a group of members from the migration project initially participated in a workshop to define a functional architecture: an architectural model that identifies features that contribute to achieving the business goals. The team members included business process analysts and business architects from the \textit{Business Change Management} team along with software architects and application developers from the \textit{Architectural Board}. Various other external consultants and experts from financial software vendors also participated in the workshop. Together they provided

\footnote{IT failure of Royal Bank of Scotland (RBS): \url{http://goo.gl/xpDjy}}
the initial blueprint of the functional architecture. Following
the first workshop, three more workshops were conducted
that resulted in identifying various business components to
realize the initial functional architecture as shown in Figure 2.
The identification of the business components, referred to as
“componentization”, was one of the initial activities to realize
potential candidate services. The notion of componentization is a way to construct a business component, which corresponds
to a feature contributing towards a business goal.

Fig. 2. Logical Target Architecture

Previously, such features were scattered over various sub-
systems. For instance, the “calculate interest” feature was
previously found in two subsystems: (i) CalculateInterest and
(ii) BalanceCheck. Earlier, “product agreements” feature was
also distributed over various subsystems. In the logical target-
architecture, related features are gathered within one logical
unit to ensure that architecture governance is easy, and to
minimize the product gaps within the payments domain.

Benefits, Challenges and Best Practices: Identifying busi-
ness components representing potential candidate services in
legacy to SOA migration is a challenging task. In this migra-
tion process, a goal-service modeling approach, proposed by
Arsanjani et al. [22], is followed. A goal-service modeling
approach is used to componentize the business component
because it ties services to the business goals. Each identified
candidate service was prioritized based on its business value.
Additionally, a catalogue for each business component was
created, indicating the degree of reusability by other compo-
nents and possible functional dependencies (coupling) with
other components in the logical architecture. Such a catalogue
provides an overview of components whose migration can be
performed independently, preferably in parallel with other
relatively independent components and hence, maximizing
parallelization of the migration process. In total, 44 different
high level features were identified.

C. Analyzing the Gap

The third phase of the migration process is to gather and
determine the information about the legacy system features
that can contribute to the realization of the logical target-
architecture. The payments domain consists of a mix of

Furthermore, to have an in-depth understanding of the
technical qualities of each COBOL program, a detailed anal-
alysis was carried out for each subsystem using proprietary
automated source code analyzers. Such a detailed analysis pro-
vided insights into individual COBOL programs within each
subsystem. For instance, individual programs were categorized
into good, bad and average based on their complexity. Figure 3
depicts an excerpt of a detailed program analysis derived
from source code analyzers of the CalculateInterest COBOL
programs. Due to space limitations, the detailed analysis is
not presented in this paper, but anonymized reports of the
CalculateInterest and the ForeignAccount are available2.

As a part of the legacy assessment, a call dependency
diagram of the subsystems was generated and analyzed based
upon number of incoming call (NIC) and number of out-
going calls (NOC). As a result, numerous computationally
intensive COBOL programs (with high NIC and high NOC)
and core libraries (with high NIC) within each subsystems

---

2http://goo.gl/1w7m9q
were identified, following the work of Geet & Demeyer [23]. Such programs were later manually investigated to locate features within the subsystems. Figure 4 depicts an excerpt of the generated call dependency diagram of the CalculateInterest subsystem in which the red-circled programs (RT23N, RT23M, RT20K and RT009), for instance, could potentially be core libraries of interest.

After the legacy assessment, an inventory of high level features available within the subsystems of the payments domain was created. The inventory of the features was created by consulting the available documentation and interviewing the technical staff of the subsystems. The latter method proved to be very useful and confirms that the knowledge residing within the organization is of the utmost importance. The inventory of the high level features was then analyzed by the Business Change Management and Architecture Board to determine the priority and business value. The features were then mapped to the logical components within the logical target-architecture via the gap analysis method [24]. The mapping was performed by focused workshops conducted for each subsystem in which business analysts, application analysts, consultants, developers and lead architects discuss and finalize the mapping of each subsystem. This mapping approach was effective such that the migration team not only identified the mappings, but also the dependencies within the high level features of the subsystems. Table III depicts an excerpt of the feature mapping of the CalculateInterest and the AccountAgreement to the logical target-architecture.

### Benefits, Challenges and Best Practices

The “analyzing the gap” phase enabled the migration team to catalogue the existing features with the aim to maximize reuse features. In particular, the use of reverse engineering tools/techniques has facilitated understanding the current legacy assets, their technical qualities, and identifying the potential features based on call dependency diagrams. The “analyzing the gap” phase has not only been effective in identifying, prioritizing and determining the granularity of existing features, but also in determining which feature is to be reused. The legacy assessment activity contributed to identifying the technical program quality in terms of software metrics such as maintainability, module coupling, duplication, changeability. Such software metrics have been extensively used in the software evolution domain, for instance, to determine the reusability factor [6]. To better understand the individual programs within each subsystem, the program level quality metrics along with the program visualization in the form of a call dependency diagrams were generated using reverse engineering tools. Furthermore, the interview sessions with the technical staff of the payments domain proved to be extremely important. Needless to say, intimate knowledge of the existing resources is essential to a successful migration, and necessary steps should be taken to harvest and preserve such existing knowledge.

### D. Realizing the Migration

The payment domain of the bank has a heterogeneous IT infrastructure with some of the features being efficient and robust with respect to performance while others being rigid commercial off-the-self (COTS) applications. In such a scenario, relying on a single approach to realize migration is not a viable solution. Thus, the migration process made the following four explicit choices for realization:

1) **Reuse and/or Upgrade**: One of the key performance indicators of a bank is accuracy and efficient processing of voluminous financial transactions. In the payments domain, some of the features are highly robust in terms of accurate and efficient processing of transactions. Such features are either reused or upgraded based on their business value and the program quality characteristics derived in the “legacy assessment” of the “analyzing the gap” phase. For example, the “calculate interest” feature is reused. With regards to the CalculateInterest subsystem, one of the business analysts says “The clear separation in the features of the CalculateInterest subsystem has eased our maintenance. Also, if we consider rebuilding or splitting the features then the impact will be very high– technically and economically and we are not sure if we can achieve the current performance. Thus, for the time being we decided to reuse the features of the CalculateInterest”.

2) **Package Replacement**: Numerous logical components within the logical target-architecture cannot be directly
mapped to existing features of the legacy applications. Thus, some of the components in the target-architecture are being replaced by a packaged solution. The decision to replace is reached by assessing the technical program qualities and economical feasibility of the feature. One of the examples of such a replacement is within the features of the ForeignAccount subsystem, which in itself is a third party packaged subsystem responsible for international payments. Thus, the features of the ForeignAccount subsystem are replaced by a packaged solution. An application architect says “ForeignAccount is a package software with very limited documentation and reusing its features will lead to long-term maintenance problems in the future. So we decided to replace it with a packaged solution”.

3) Customized Replacement: With the introduction of the Euro currency, various laws and regulations within the payment domain have changed in the European Union. The bank has to comply with such changes. One of the business consultants emphasizes the importance of the SEPA stating that “SEPA is one of the triggers for the renewal of the whole payments infrastructure. It is also one of the main business drivers for lowering cost. Such crucial features have to be custom-built so that its maintenance and upgrade in the future will be easy for us”.

4) Outsourcing: The final option is to outsource an entire feature to an external party for development. This option is chosen only if outsourcing contributes to the strategic objectives of Payments (such as cost reduction) and must fulfill the requirements as formulated in the outsourcing strategy-guidelines to ensure that outsourcing is done via strategic partners and only when no other option is viable. A lead architect explains the need of outsourcing as “Features that are of low business value and can be developed cheaply are outsourced such as card authorization and card payments. This helps us to focus on the high priority features.”

The selection of an appropriate realization option is based on various factors such as business value of the logical component, technical quality of the legacy assets, cost of implementation and the importance of ease of upgrading/updating.

Benefits, Challenges and Best Practices: Realization of the migration is the starting point of implementing the logical components. Realization is not only about deciding which programming language is to be used, but also the associated environment such as hardware and operating system. The other factor that contributes to the success of realization is the determination of the suitable granularity of the potential candidate services. In this migration project, there were predefined guidelines provided by the program management committee on deciding which realization option to use. The guidelines were developed by considering “external vs internal development” and “adoption of existing vs new technology”. Figure 5 depicts the realization options based on development and technology adoption criteria.
A crucial criterion to determine the realization option was the business value and priority of the logical component. For instance, central to NedBank’s business are the calculation of interest, commission and cost calculation features. The logical components encompassing these features are reused and/or upgraded from the existing ones. Upon deciding to reuse and/or upgrade, the technical qualities of the features are examined to estimate the migration time. It was not always simple to reuse or upgrade, particularly for third party packaged solutions that are not updated or supported by the vendor anymore. For instance, the vendor who developed COBOL running in HP Tandem Nonstop went through various mergers and acquisitions such that the infrastructure is hardly updated and maintained. In such cases, a suitable packaged replacement is preferred. Any new logical component with high business value falls under the “Customized Replacement” option. A low priority logical component is outsourced to a third party upon strictly fulfilling the “outsourcing” criteria.

V. LESSON LEARNED

A. Implications of Reverse Engineering Techniques

The reverse engineering techniques that are used in this migration project had a significant role in finding the facts of the current legacy programs and subsystems. In particular, the use of such techniques in the “analyzing the gap” phase to obtain various metrics and call dependency graphs not only facilitated the creation of an inventory of the current assets, but also identified computationally intensive COBOL programs. In addition to creating an inventory of the current assets, using reverse engineering techniques has the following two implications:

(i) Assisting in Selecting the Realization Approach: The use of reverse engineering techniques has strongly facilitated the selection of the realization approaches in the migration process. The migration team used the program quality metrics generated by the reverse engineering tools to estimate the complexity of the programs. For example, in Figure 3, the COBOL program RT01600 has high McCabe complexity and a negative maintainability index (MI). Hence, RT01600 is a potential candidate of replacement unless it has a low business priority. Similarly, programs with good and average index have potential for reuse. In case of identifying candidate COBOL programs for services, the generation of call dependency graphs of the subsystems was helpful. For instance, based on the work of Van Geet et al. [23], the red-circled programs (RT23N, RT23M, RT20K and RT009) of Figure 4, were COBOL programs of interest as they have high number of incoming calls (NIC). Thus, upon generating and analyzing the call dependency graph those programs were investigated by the existing programmers to identify their functionalities.

(ii) Knowledge Harvesting: Most of the documentation of the subsystems was either outdated or incomplete. With the results of the reverse engineering techniques, a considerable amount of new information about the programs was identified that were even unknown to the current maintainers of the subsystems. For instance, 599 out of 21085 copybooks are not used by the “CalculateInterest” subsystem. This finding was a surprise to the current maintenance team of the subsystem. Additionally, the flow graphs were generated to understands the overall flow of the programs within the subsystem. These artifacts helped to update the documentation.

B. Adopting a Pragmatic Realization Approach

In the realization phase of the migration process, a pragmatic approach for executing the migration is adopted in which the choices are based on various factors such as business value, business priority, and the technical qualities of the features. The initial choice of reusing the existing functionalities is one of the notable benefits claimed by the proponents of SOA for leveraging existing assets. However, in a large scale legacy application, reuse is not always feasible. Therefore, the migration process of NedBank suitably adapted other possible realization methods for a successful migration. Additionally, for large scale legacy applications that include heterogeneous IT infrastructures (diverse programming languages, various hardware and operating systems) there is no silver bullet solution to realize the migration process. For a successful migration process, any approach can contribute to the success of the migration, provided that the approach is well defined, and suited for the enterprise.

C. Emphasizing Organizational and Business Perspectives

Migration from legacy to a SOA environment is not only a technical endeavor, but also involves significant issues from the organizational and business perspective. Particularly in the case of legacy systems having no or outdated documentation, early involvement of existing technical staff in the migration process is proven to be useful. The involvement of the technical staff facilitates the knowledge transfer to the migration team. The synergy between the technical staff and the migration team that was observed in this migration process was one of the key factors contributing towards the success of the migration. Equally important is the focus of the “Program Management Committee” in the business-IT alignment that facilitated the migration to achieve the business goals. An important lesson learned is that technical staff tends to resist change because they fear that their expertise and professional experience with legacy systems may become redundant due to
the introduction of SOA. Therefore, it is important to involve
the technical staff from the start of the migration process and
provide necessary training to adapt to new technology. In
the current migration process, the formation of various teams
under the “Program Management Committee” has actively
involved the technical staff whose knowledge about the legacy
systems have proven to be of significant importance.

D. Harvesting Knowledge to Prevent Knowledge Erosion

Apart from available documentation, existing knowledge in
the form of skills and experience within the technical staff
is one of the most important assets. Over the years, such
knowledge and skills become scarce resulting in knowledge
erosion due to factors such as ageing, and staff changing jobs.
Hence, suitable strategies such as conducting and archiving
interviews, and initiating knowledge transfer programs via
training should be undertaken to harvest and preserve such
existing knowledge. In the migration process of NedBank, the
involvement of the technical staff in the migration process has
significantly helped in knowledge harvesting and preservation
while creating inventories of the high level functionalities
of the subsystems. Some of technical staff were interviewed
and focused training programs were organized to facilitate
knowledge transfer. Additionally, the existing documentation
was updated or created in case if no documentation exists.

VI. CONCLUSION

In this paper, we present the findings of a case study of
a large scale legacy to SOA migration process within
the payments domain of a Dutch financial institution. The paper
presents the business drivers that initiated the migration, and
describes a 4-phase migration process. The migration process
equally focuses on the technical and the business &
organizational aspects of the migration. The migration process
starts by forming a “Program Management Committee” for
proper governance. Then, a logical-target architecture is develop-
osed based on the concept of componentization. The business
components within the logical target-architecture are aligned
to support the business goals. The logical target-architecture
is then mapped to the existing legacy features using a gap
analysis method. Such a gap analysis suitably supports the
potential of reusing the legacy features without significant
changes to the legacy systems itself— one of the key promises
of the SOA. The migration is then realized following the
pragmatic realization options of the migration process.

The paper presents an industrial report detailing how reverse
engineering techniques were employed to facilitate a large
scale legacy to SOA migration process. It illustrates the pain of
the practicalities and under-emphasized aspects of a large scale
migration project, and should be considered a call-to-action
for computer scientists to study the project environment, both
from a business and organizational point of view, as much as
they study the technical aspects of migration.

As to future research, we aim to exploit model-driven
modernization approaches to extract features from the sub-
systems. Another interesting research area is to investigate
how to automatically translate legacy applications to a modern
language.
